Pension Scheme Administration Platform

Compact Business Vision — My Understanding

In one sentence: Build a secure, centralized digital platform that replaces fragmented, manual pension administration with controlled workflows for schemes, employers, members, contributions, pension accounts, investments, benefits and reporting.

1. The business problem

The current process is described as manual and spreadsheet-driven, with limited centralized reporting and auditability. This can cause duplicate data entry, inconsistent records, slow reconciliation, limited visibility and difficulty proving who changed or approved a transaction. These are problems to validate against the real current-state process.

2. What the platform should do

Capability	Business outcome
Scheme management	Configure scheme details, eligibility, rules, status and effective dates.
Employer management	Register employers, maintain authorized contacts and associate them with schemes.
Member management	Enroll eligible members, maintain records and prevent duplicate or invalid registrations.
Contributions and accounts	Record submissions, receipts and allocations; reconcile differences and track exceptions.
Investment records	Maintain approved investment and allocation records; actual trading may be outside scope.
Benefits administration	Validate requests, route approvals and record decisions and payment outcomes.
Reporting and audit	Provide operational/financial reports and traceable records of material actions.

3. Who uses it?

Primary users: pension administrators, employers and members. **Supporting users:** operations, finance, compliance, IT support and management. Access should be role-based; submitting, reviewing and approving sensitive financial or benefit actions may need to be separated.

4. Core business controls

Each scheme and member needs an agreed unique identity. Enrollment must follow scheme eligibility rules. Contributions must be traceable to the relevant employer, member and scheme. Submitted, received and allocated amounts must be reconcilable. Material changes need an audit trail. Unmatched amounts, invalid records and failed transactions must be flagged and resolved rather than silently marked complete.

5. What success means

The source vision proposes a 90% reduction in manual entry, 95% data accuracy and 99.5% availability. Treat these as provisional targets until the business defines each metric, establishes a current baseline, confirms the measurement period and assigns an owner. Additional useful measures include reconciliation turnaround, exception-resolution time, enrollment processing time and audit completeness.

6. Scope boundaries

Likely in scope: scheme, employer, member, pension-account, contribution, investment-record, benefit-workflow and reporting administration. **Initially out of scope unless approved:** payroll processing, tax calculation, banking infrastructure, investment trading and actuarial modelling. External systems may still be integrated through controlled interfaces if separately agreed.

7. Decisions to confirm before design

- Pension type: defined-contribution, defined-benefit, statutory or another model.
- Governing country, regulator and applicable scheme rules.
- Whether the platform only records payments or initiates them.
- Exact benefit types and who calculates/approves them.
- Existing systems, migration data, integrations and data-retention rules.
- Expected user/transaction volumes, security requirements, recovery targets and service levels.

8. How this feeds the project

Business Vision → BRD → Domain Model → ERD → HLD → LLD → Development & Testing. The vision explains why the platform exists and its business boundaries. The BRD should turn validated capabilities into testable requirements. The domain model and ERD should represent approved business concepts and relationships; HLD/LLD then define implementation. AI-generated designs must not invent unapproved rules or features.

My overall understanding: This is not simply a member-registration application. It is a controlled pension-administration system where reliable records, financial reconciliation, permissions, auditability and benefit-processing governance are as important as the user interface.

Note: This is a concise interpretation of the supplied business vision, not a validated legal, regulatory or scheme-specific specification.
